RAM and a probability of receiving a royal straight flush in the first round of dealing 5 cards. The probability of a royal straight flush in the first round of dealing 5 cards in Texas Hold'em, for example, can be calculated in the following form: There are 4 ways to form a royal straight flush (one for each suit).

For each suit, there are 4 cards with the value 10, 3 with the value J, 2 with the value Q and only 1 with the value K. Therefore, there are exactly $4 \times 3 \times 2 \times 1 = 24$ ways to complete a sequence. However, we must consider that the 5 cards must be distinct. This means that we divide the total number of combinations by 5! (factorial of 5), resulting in $C(52, 5) = 2.598.960$. From this form, the probability of receiving a royal straight flush is:

A quina is a simple lottery game where the player selects a certain interval, generally between 1 to 80. The objective is to win the exact sequence of five numbers drawn, but it is possible to win prizes for smaller sequences. The quina is a lottery game that is held twice a day, once in the morning and once at night. The results can be checked on specialized sites, newspapers or TV channels that transmit the results live. In addition, it is possible to verify the results previously published in authorized stores. To play the quina, it is enough to select five numbers and place a bet with a qualified agent. It is possible to make only one bet or acquire multiple tickets to increase the chances of winning. In addition, there are various strategies and theories about how to choose the numbers, but it is important to remember that the quina is a lottery game and, therefore, it is a game of chance.
